1. MEDIA SUMMARY

The brassica industry has developed an integrated approach to weed control with cultural and herbicide methods used to keep weed populations at low levels such that economic crops can be grown. However there are no herbicides registered for post-emergence broadleaf weed control in brassica crops, other than at very early post-transplanting.

This project aimed at evaluating possible alternatives for later post-emergence weed control in cauliflower, broccoli and Brussels sprouts.

A range of herbicides and herbicide application programs were evaluated at eight locations in the major brassica growing areas of Australia.

The program confirmed that the application of BARON WP (oxyfluorfen) herbicide as a broadcast treatment to be a very effective tool when applied within 3 days following transplanting as per the label recommendations in a program with a suitable pre-emergence herbicide such as DUAL GOLD (S-metolachlor).

Investigation of the benefits of applying BARON WP at 3-4 weeks following transplanting demonstrated no difference over and above applying BARON WP immediately following transplanting, when applied accurately.

The need to control broadleaf weeds which 'escape' early weed control strategies was further addressed through the use of the non-selective knockdown herbicides glufosinate-ammonium (BASTA), carfentrazone-ethyl (SPOTLIGHT PLUS) and paraquat (GRAMOXONE 250) as well as BARON WP through shrouded sprayers. BARON WP applied through a shrouded sprayer as an alternative to applying the treatment 'over the top' would be effective.

However, the major concern is with spray drift escaping from the unit and causing damage to the off-target crop. A level of crop phytotoxicity was seen in all trials, and was particularly severe at some locations. A level of precision is required when applying treatments in this fashion which may be beyond the capability of currently available shrouded spraying equipment. The use of non-selective herbicides through this method of application however will offer growers a practical alternative to cultivation later in the crop cycle but effective shrouded sprayers for vegetable brassicas need to be developed.

The use of BASTA (glufosinate-ammonium) applied via shrouded sprayers gave effective weed control and will offer an alternative to residual herbicides or cultivation. The further development of this form of weed control is recommended.

GRAMOXONE 250 currently has a registration for use via shielded equipment in vegetables and could be used as a salvage treatment where equipment is available.

SPOTLIGHT PLUS (carfentrazone-ethyl) is not recommended for further development via this application technique.

2. TECHNICAL SUMMARY

The brassica industry has developed an integrated approach to weed control with cultural and herbicide methods used to keep weed populations at low levels such that economic crops can be grown. However there are no herbicides registered for post-emergence broadleaf weed control in brassica crops, other than at very early post-transplanting.

This project aimed at evaluating herbicide options for later post-emergence weed control, or strategies using currently registered herbicides to provide effective weed control in Brussels sprouts, cauliflower and broccoli.

Eight small plot replicated field trials were conducted in the major brassica growing regions of Australia to evaluate the currently registered herbicide BARON WP (oxyfluorfen) when applied at crop stages later than are currently registered, when applied in a program with currently registered pre-emergence herbicides, and when applied as a banded in-row treatment using shrouded spray equipment. In addition the pre-emergence herbicide FRONTIER-P (dimethenamid-P) was included at a number of locations as an alternative to currently registered actives.

A further four small plot replicated field trials were conducted to evaluate the non-selective knockdown herbicides BASTA (glufosinate-ammonium), GRAMOXONE 250 (paraquat) and SPOTLIGHT PLUS (carfentrazone-ethyl) when applied alone or in combination with BARON WP (oxyfluorfen) through shrouded spray equipment for later post-emergent weed control.

A fully compliant GLP residue program was also conducted with the active ingredients used in this part of the program to generate crop residue data, when each of these active was applied at these timing via shrouded equipment.

Efficacy trials were conducted as small plot replicated experiments with 3 or 4 replicates. Treatments were applied at the appropriate timings using hand held gas operated boom sprayers as broadcast or directed (shroud) spray treatments. Application volumes were used which replicated industry standards. Assessments for post-application weed control and crop safety were conducted at each location and crop yield measured at two sites.

In these studies over 22 different broadleaf weeds were present with *Stellaria media*, *Sonchus oleraceus*, *Chenopodium album* and *Malva parviflora* being the most ubiquitous.

The application of BARON WP herbicide as a broadcast treatment was shown to be a very effective tool when applied as a broadcast spray within 3 days following transplanting as per the label recommendations in a program with a suitable pre-emergence herbicide such as DUAL GOLD (S-metolachlor).

Investigation of the benefits of applying BARON WP at 3-4 weeks following transplanting demonstrated no difference over and above applying BARON WP immediately following transplanting. Whilst the treatments were generally considered safe, at some locations a significant reduction in crop biomass compared to untreated plots was seen. The use of the BARON WP alone to achieve later post-emergence weed control cannot be supported.

The herbicide FRONTIER-P (dimethenamid-P) was also evaluated as an alternative to the currently used pre-emergence herbicides. Whilst effective weed control was achieved, data indicated that performance was generally less than the current standards where applied alone or in a program with BARON WP. In addition some crop safety issues were identified with FRONTIER-P generally showing a lower level of selectivity than the current standards and as such cannot be recommended for further development.

The need to control broadleaf weeds which ‘escape’ early weed control strategies was further addressed through the use of the non-selective knockdown herbicides BASTA (glufosinate-ammonium), SPOTLIGHT PLUS (carfentrazone-ethyl) and GRAMOXONE 250 (paraquat) as well as BARON WP through shrouded sprayers. BARON WP applied through a shrouded sprayer as an alternative to applying the treatment ‘over the top’ would be effective. Application rates of 150-500 g/ha were safe but generally were no better than when BARON WP was applied at transplanting.

The use of BASTA (glufosinate-ammonium) applied via shrouded sprayers gave effective weed control and will offer an alternative to residual herbicides or cultivation. The further development of this form of weed control is recommended.

The major concern however is with spray drift escaping from the unit and causing damage to the off-target crop. A level of crop phytotoxicity was seen in all trials but varied between locations. General damage was greatest at 7 days following application and disappeared over time. When tank-mixed with BARON WP however phytotoxic symptoms were often greater than with each of the knockdown herbicides applied alone. A tank mix of BARON WP plus either BASTA, SPOTLIGHT PLUS or GRAMOXONE 250 cannot be recommended for further development due to the high risk of a significant level of crop damage occurring.

GRAMOXONE 250 currently has a registration for use via shielded equipment in vegetables and could be used as a salvage treatment where equipment is available.

SPOTLIGHT PLUS (carfentrazone-ethyl) is not recommended for further development via this application technique.

3. INTRODUCTION

All brassica crops require good weed control, especially during the establishment period, as the seedlings are delicate and uncompetitive with weeds. Weeds compete for space, sunlight, nutrients and water. Weeds in the near vicinity of brassica crops and within paddocks can sometimes harbour pathogens, insects or vertebrates that can invade and spread to the crop soon after planting. As brassica crops develop, especially cauliflower and Brussels sprouts, they have the ability to shade and compete well with weeds; broccoli on the other hand produce little shade.

The brassica industry has developed an integrated approach to weed control with cultural and herbicide methods used to keep weed populations at low levels such that economic crops can be grown. Management of diseases, insects and nematodes also have an effect on the weed control program because damage by pests may limit the crop's overall ability to compete with weeds and sometimes makes the crop more susceptible to herbicides.

According to a report to Horticulture Australia Ltd (Frost et al 2002) the options for weed control in brassica crops is limited. Mechanical methods are the principle means of weed control in Victoria, South Australia and Western Australia. In Queensland, New South Wales and parts of Tasmania (broad-acre systems), herbicides are increasingly being used for weed control.

Mechanical weed control methods employed after planting often cause physical damage. Cultivation can also contaminate crops with soil resulting in the potential spread of Xanthomonas (Frost et al 2002) and other diseases.

A thorough investigation of the herbicides employed in the industry and their use patterns was conducted by AgAware consulting in 2007/2008 (VGO6107). The study surveyed registered herbicides at that time and drew the following conclusions;

“Some pre-emergent herbicides are applied before transplanting or seeding and some are applied immediately after transplanting or seeding. These herbicides require irrigation before application if soils are dry and also require irrigation soon after application to ‘lock’ the herbicide into the top few centimetres of soil so that germinating weed seedlings are killed. There are no herbicides registered for post-emergence broadleaf weed control in brassica crops (Dimsey 1998), other than at very early post-transplanting. LONTREL (clopyralid) has a permit for use in cauliflower for capeweed and clover control for Western Australia only.”

Little has changed since that time.

The report went on to make the following recommendations as a means of extending the weed controls options available to vegetable brassica growers:

- Investigate the use of BARON WP (oxyfluorfen) applied at low use rates as a post-emergence treatment several weeks after transplanting for broccoli, cauliflower and Brussels sprouts. The use of oxyfluorfen in this manner would lower the costs of weed control to grower as well as reduce the pesticide load currently used.
- The possible use of the knockdown herbicides BASTA (glufosinate-ammonium) or GRAMOXONE 250 (paraquat) in combination with low rates of oxyfluorfen or SPOTLIGHT PLUS (carfentrazone-ethyl) as post-emergence treatments applied by shielded sprayers between rows of brassica crops.
- Conduct research with oxyfluorfen post-emergence and post-transplant plus and minus irrigation to demonstrate to growers the importance of herbicide incorporation for weed control.
- The production of a ‘Growers Manual’ listing ‘best-practice’ techniques for using the currently available herbicides.

This project was formulated based upon these recommendations and included the following components:

Project Component 1 – Herbicide Strategies

Under this part of the project eight field trials were conducted in each of the major brassica growing areas within Australia to evaluate the use of BARON WP (oxyfluorfen) as an option for later post-emergence weed control when applied as a broadcast spray. In addition the previously identified selective herbicide FRONTIER-P (dimethenamid-P) was included at some sites to evaluate efficacy and selectivity.

Project Component 2 – Knockdown Shielded Herbicide Program

The efficacy and safety of several different herbicides when applied through protected spraying equipment was evaluated at five locations. Shrouded booms were constructed to simulate commercial application and the candidates; glufosinate-ammonium, paraquat, carfentrazone-ethyl and oxyfluorfen applied.

A full residue program was also completed including each of the above actives. Eight sites were established and each of the herbicides applied using the shrouded boom equipment at around 5 weeks following transplanting. Crop samples were harvested and analysed for each of the actives evaluated.

A fully compliant GLP residue report has been prepared and has been submitted as an addendum to this report.

Project Component 3 – Irrigation Incorporation Demonstration

The importance of incorporating the herbicide BARON WP (oxyfluorfen) when applied as an early post-transplant treatment was demonstrated at five locations by maintaining incorporated and non-incorporated herbicide plots.

Project Component 4 – Grower Resource Pack

A grower resource document was prepared detailing options for integrated weed management in these crops. The brochure is included as an Addendum to this report.

In addition field days were held at each site to demonstrate various herbicide options for weed control as well as stressing the importance of adopting an integrated approach to weed management.

The project was conducted under Horticulture Australia Limited project VG09137 and Agrisearch Project HAL/09/06/a.

4. MATERIALS AND METHODS

4.1 Project Component 1 – Herbicide Strategies

4.1.1 Site Details

Trial Number	Location	Soil Type	Crop	Variety	Experimenter	Transplant Date
1	Gatton, Qld	Black self mulching clay	Broccoli	Atomic	Richard Holzknecht	10-Feb-10
2	Mangrove Mountain, NSW	Sandy loam	Broccoli	Greenbelt	Peter Melville	27-Apr-10
3	Bathurst, NSW	Granitic sandy clay	Cauliflower	Beluga	Neil Adams	24-Feb-10
4	Coldstream, Vic	Grey clay loam	Brussels sprouts	Oliver	Marco Montagna	1-Feb-10
5	Werribee, Vic	Red clay loam	Cauliflower	Skywalker	Marco Montagna	22-Feb-10
6	Devonport, Tas	Red clay loam	Broccoli	Iron man	Philip Frost (Peracto)	4-Mar-10
7	Nairne, SA	Brown clay loam	Brussels sprouts	Millennium	Bill Frost	20-Jan-10
8	Manjimup, WA	Sandy loam	Cauliflower	Skywalker	Charlie Hewitt	10-Mar-10

4.1.2 Target Weeds

Trial Number	Location	Weeds
1	Gatton, Qld	Black pigweed (<i>Trianthema portulacastrum</i>), sowthistle (<i>Sonchus oleraceus</i>), dwarf amaranth (<i>Amaranthus macrocarpus</i>), barnyard grass (<i>Echinochloa crus-galli</i>)
2	Mangrove Mountain, NSW	Potato weed (<i>Galinsoga parviflora</i>), chickweed (<i>Stellaria media</i>), shepherd's purse (<i>Capsella bursa-pastoris</i>), marshmallow (<i>Malva parviflora</i>), winter grass (<i>Poa annua</i>)
3	Bathurst, NSW	Saffron thistle (<i>Carthamus lanatus</i>), chickweed (<i>Stellaria media</i>), pigweed (<i>Portulaca oleracea</i>), deadnettle (<i>Lamium amplexicaule</i>), Paterson's curse (<i>Echium plantagineum</i>), shepherd's purse (<i>Capsella bursa-pastoris</i>)
4	Coldstream, Vic	Fat hen (<i>Chenopodium album</i>), capeweed (<i>Arctotheca calendula</i>), wireweed (<i>Polygonum aviculare</i>), marshmallow (<i>Malva parviflora</i>), annual ryegrass (<i>Lolium rigidum</i>)
5	Werribee, Vic	Stinging nettle (<i>Urtica urens</i>), shepherd's purse (<i>Capsella bursa-pastoris</i>), wireweed (<i>Polygonum aviculare</i>), marshmallow (<i>Malva parviflora</i>), sowthistle (<i>Sonchus oleraceus</i>)
6	Devonport, Tas	Fat hen (<i>Chenopodium album</i>), blackberry nightshade (<i>Solanum nigrum</i>), shepherd's purse (<i>Capsella bursa-pastoris</i>), Opium poppy (<i>Papaver somniferum</i>)
7	Nairne, SA	Fat hen (<i>Chenopodium album</i>), wireweed (<i>Polygonum aviculare</i>), capeweed (<i>Arctotheca calendula</i>)
8	Manjimup, WA	Wild radish (<i>Raphanus raphanistrum</i>), dock (<i>Rumex</i> sp), arrow leaf clover (<i>Trifolium vesiculosum</i>), fat hen (<i>Chenopodium album</i>), annual ryegrass (<i>Lolium rigidum</i>)

DAT = days after transplanting; WAT = weeks after transplanting

***Pre-em Herbicide:** The following herbicides were used in these trials prior to transplanting, or immediately post-transplanting (0-2 DAT):

DUAL GOLD (S-metolachlor) – 1500 mL/ha applied immediately following transplanting in sites 3 and 7 and 2000 mL/ha in sites 1, 2, 4, 6 and 8.

RIFLE 330 (pendimethalin) – 2500 mL/ha applied and incorporated by irrigation prior to transplanting in site 5.

4.1.4 Formulations

NUFARM RIFLE 330 HERBICIDE – an emulsifiable concentrate formulation containing 330 g/L pendimethalin as marketed by Nufarm Australia Limited.

DUAL GOLD HERBICIDE – an emulsifiable concentrate formulation containing 960 g/L S-metolachlor as marketed by Syngenta Crop Protection Pty Ltd.

BARON 400 WP SELECTIVE HERBICIDE – a wettable powder formulation containing 400 g/kg oxyfluorfen as marketed by Agnova Technologies Limited.

FRONTIER-P HERBICIDE – a liquid concentrate formulation containing 720 g/L dimethenamid-P as supplied by Serve-Ag Pty Ltd.

NUFARM RAMROD FLOWABLE HERBICIDE – a suspension concentrate formulation containing 480 g/L propachlor as marketed by Nufarm Australia Limited.

4.1.5 Application Method

Broadcast Treatments

Trial Number	Location	Equipment	Nozzles	Pressure	Volume/ha
1	Gatton, Qld	Hand boom	11001 flat fan	290 kPa	209 L
2	Mangrove Mountain, NSW	Hand boom	11001 flat fan	210 kPa	80 L/400 L

4.1.6 Experimental Design

Trial Number	Location	Trial Design	Replicates	Plot size
1	Gatton, Qld	RCB	3	1 bed, 4 rows (1.5 m) X 5 m
2	Mangrove Mountain, NSW	RCB	3	1 bed, 4 rows (1.5 m) X 5 m
3	Bathurst, NSW	RCB	4	1 bed, 4 rows (1.5 m) X 5 m
4	Coldstream, Vic	RCB	3	1 bed, 2 rows (1.5 m) X 5 m
5	Werribee, Vic	RCB	3	1 bed, 4 rows (1.5 m) X 5 m
6	Devonport, Tas	RCB	3	2 m x 6 m
7	Nairne, SA	RCB	3	1 bed, 2 rows (1.5 m) X 5 m
8	Manjimup, WA	RCB	3	1 bed, 4 rows (1.5 m) X 5 m

4.1.7 Assessments

Timing*	Assessment
1 WAT	Crop phytotoxicity
2-3 WAT	Crop phytotoxicity, percentage weed control
4-5 WAT	Crop phytotoxicity, weed count, percentage weed control
6-8 WAT#	Crop phytotoxicity, percentage weed control
10 WAT#	Crop biomass reduction

*Approximate timings - Assessments commenced around 1 week following the final post-emergence herbicide application which was around 3-4 weeks following transplanting

not done at all sites

Weed Control

Weed control assessments were completed on 3-4 occasions. A visual assessment of weed biomass reduction (% control) was completed for each species. Results are given as the mean percentage control. At around 4 WAT a quadrat count was taken and the total number of weeds by species counted. Results are given as the mean number of weeds per square metre.

Phytotoxicity/Crop Damage

Inspections for crop phytotoxicity were conducted at each visit to the trial sites. Where symptoms were seen crop effects were rated using a 0-100 percentage scale as follows:

0 = no effects evident

10 = 10% leaf area showing signs of leaf damage/spotting

50 = 50% leaf area showing signs of leaf damage/spotting

100 = plants dead

Crop Vigour Effects

Inspections for the effect of treatment on crop vigour was conducted at each visit to the trial sites. Where effects were seen plots were scored for relative crop vigour or biomass relative to the most vigorous plot in that replicate. Results are given as relative crop vigour using a 0-100 scale where 100 = most vigorous plot in each replicate 50 = 50% reduction in biomass and 0 = plants dead.

4.2 Project Component 2 – Knockdown Shielded Herbicide Program

4.2.1 Efficacy Studies

4.2.1.1 Site Details

Trial Number	Location	Soil Type	Crop	Variety	Experimenter	Transplant Date

4	Nairne, SA	Shrouded boom	9404 EVS flat fan	200 kPa	400 L/sprayed ha

4.2.1.6 Experimental Design

Trial Number	Location	Trial Design	Replicates	Plot size
1	Gatton, Qld	RCB	3	1 bed, 4 rows (1.5 m) X 5 m
2	Mangrove Mountain, NSW	RCB	3	1 bed, 4 rows (1.5 m) X 5 m
3	Werribee, Vic	RCB	3	1 bed, 4 rows (1.5 m) X 5 m
4	Nairne, SA	RCB	3	1 bed, 2 rows (1.5 m) X 5 m

4.2.1.7 Assessments

Timing*	Assessment
1 WAT	Crop phytotoxicity
4-5 WAT	Weed count, percentage weed control, crop phytotoxicity
6-8 WAT	Weed count, percentage weed control, crop phytotoxicity
Commercial harvest	Crop yield (sites 2 and 3 only)

*Approximate timings – Assessments commenced around 1 week following the final post-emergence herbicide application which was around 3-4 weeks following transplanting.

Weed Control

Weed control assessments were completed on 3-4 occasions. A visual assessment of weed biomass reduction (% control) was completed for each species. Results are given as the mean percentage control. At around 4 WAT a quadrat count was taken and the total number of weeds by species counted. Results are given as the mean number of weeds per square metre.

Phytotoxicity/Crop Damage

Inspections for crop phytotoxicity were conducted at each visit to the trial sites. Where symptoms were seen crop effects were rated using a 0-100 percentage scale as follows:

- 0 = no effects evident
- 10 = 10% leaf area showing signs of leaf damage/spotting
- 50 = 50% leaf area showing signs of damage/spotting
- 100 = plants dead

Crop Vigour Effects

Inspections for the effect of treatment on crop vigour was conducted at each visit to the trial sites. Where effects were seen plots were scored for relative crop vigour or biomass relative to the most vigorous plot in that replicate. Results are given as relative crop vigour using a 0-100 scale where 100 = most vigorous plot in each replicate 50 = 50% reduction in biomass and 0 = plants dead.

Crop Yield

Total yield was assessed at two sites, namely Werribee and Mangrove Mountain. All harvestable plants in each plot were cut and weighed over the 2-3 harvest dates at each site. Results are given as the yield for each assessment date as well as total yield.

4.2.2 Residue Studies

4.2.2.1 Site Details

Trial Number	Location	Soil Type	Crop	Variety	Principal Investigator	Transplant Date
1	Gatton, Qld	Black self mulching clay	Broccoli	Atomic	Richard Holzknecht	1-Mar-10
2	Mangrove Mountain, NSW	Sandy loam	Broccoli	Greenbelt	Peter Melville	27-Apr-10
3	Bathurst, NSW	Granitic sandy clay	Cauliflower	Beluga	Neil Adams	24-Feb-10
4	Coldstream, Vic	Grey clay loam	Brussels sprouts	Oliver	Samantha Strano	1-Feb-10
5	Werribee, Vic	Red clay loam	Cauliflower	Skywalker	Samantha Strano	24-Feb-10
6	Forth, Tas	Red clay loam	Broccoli	Iron man	Belinda Ingram (Peracto)	4-Mar-10
7	Nairne, SA	Brown clay loam	Brussels sprouts	Millennium	Bill Frost	20-Jan-10
8	Manjimup, WA	Sandy loam	Cauliflower	Skywalker	Charlie Hewitt	10-Mar-10

4.2.2.2 Treatments

Treatment	Rate Product/ha	Application Timing
1. Untreated control		
2. BARON WP	500 g 500 g (shielded)	2-3 DAT 3-4 WAT
3. BARON WP	500 g (shielded)	3-4 WAT
4. SPOTLIGHT PLUS	300 mL (shielded)	3-4 WAT
5. BASTA	2.5 L (shielded)	3-4 WAT
6. GRAMOXONE 250	0.8 L (shielded)	3-4 WAT

DAT = days after transplanting; WAT = weeks after transplanting

4.2.2.3 Formulations

BARON 400 WP SELECTIVE HERBICIDE – a wettable powder formulation containing 400 g/kg oxyfluorfen as the active constituent. The sample was supplied by Agnova Technologies Pty Ltd.

BASTA NON-SELECTIVE HERBICIDE – a soluble liquid concentrate formulation containing 200 g/L glufosinate-ammonium as the active constituent. The sample was supplied by Bayer CropScience Pty Ltd.

SPOTLIGHT PLUS HERBICIDE – an emulsifiable concentrate formulation containing 60 g/L carfentrazone-ethyl as the active constituent. The sample was supplied by FMC Chemical Sprl.

GRAMOXONE 250 HERBICIDE – a soluble liquid formulation containing 250 g/L paraquat present as paraquat dichloride. The sample was as marketed by Syngenta Crop Protection Pty Ltd.

4.2.2.4 Application Method

Treatments were applied in a manner which simulated commercial practice for application of herbicides in vegetable brassicas. Broadcast treatments were applied using a standard hand held boom sprayer, in a water volume of 226 L/ha to 503 L/ha which is representative of commercial application. Inter-row knockdown herbicide applications were completed using a shielded boom sprayer. The boom sprayer was purpose built to allow the application of herbicide along the inter-row space and protect the surrounding brassica plants from drift. The treatments were applied using an application of 220 L/ha to 546 L/ha into the band sprayed area.

4.2.2.5 Experimental Design

Trial Number	Location	Trial Design	Plot Size
1	Gatton, Qld	Unreplicated single plot	2 m X 5 m
2	Mangrove Mountain, NSW	Unreplicated single plot	1.5 m X 2 m
3	Bathurst, NSW	Unreplicated single plot	4 m X 5 m
4	Coldstream, Vic	Unreplicated single plot	2 m X 10 m
5	Werribee, Vic	Unreplicated single plot	2m X 10 m
6	Forth, Tas	Unreplicated single plot	2 m X 8 m
7	Nairne, SA	Unreplicated single plot	1.5 m X 10 m
8	Manjimup, WA	Unreplicated single plot	1.65 m X 7 m

4.2.2.6 Sampling Schedule

Residue sampling was completed at commercial harvest at each site.

Twelve broccoli inflorescences with stem were sampled from 12 individual broccoli plants with a minimum weight of 1 kg of each treatment for each sample.

At least 1 kg of Brussels sprouts were sampled from 12 individual Brussels sprouts plants of each treatment for each sample.

At least 12 cauliflower heads were sampled from 12 individual cauliflower plants with a minimum weight of 1 kg of each treatment for each sample.

4.2.2.7 Residue Analysis

All samples were processed and analysed by Agrisearch Analytical, Unit 1, Victoria Road, Rozelle, NSW.

Oxyfluorfen residues were determined according to an analytical method developed by Agrisearch Analytical Pty Ltd:

“Determination of Multi-Pesticide Residues in Plant using DSPE” AATM-S-60.1, Revision 1, Agrisearch Analytical Pty Ltd, 18 May 2010

Carfentrazone-ethyl residues were determined according to the following analytical method supplied by FMC Corporation:

“Analytical Methodology for the Determination of F8426 and its Acid Metabolites in/on Spring Wheat Forage, Straw and Grain”, Method No. P-3041M, FMC Corporation, Agricultural Products Group, August 1995.

Glufosinate-ammonium residues were determined according to an analytical method developed by Agrisearch Analytical Pty Ltd:

“Determination of Glufosinate and Metabolites MPPA and N-acetyl Glufosinate in Plant Material by LC-MS/MS”, AATM-S-78.1, Revision 1, Agrisearch Analytical Pty Ltd, November 2010

Paraquat residues were determined according to an analytical method developed by Agrisearch Analytical Pty Ltd:

“Determination of Diquat and Paraquat Residues in Tree Nuts” AATM-S-79, Revision 1, Agrisearch Analytical Pty Ltd, August 2007

4.3 Project Component 3 - Irrigation Incorporation Demonstration

4.3.1 Site Details

Trial Number	Location	Soil Type	Crop	Variety	Experimenter	Transplant Date
1	Gatton, Qld	Black self mulching clay	Broccoli	Atomic	Richard Holzknecht	1-Mar-10
2	Bathurst, NSW	Granitic sandy clay	Cauliflower	Beluga	Neil Adams	24-Feb-10
3	Werribee, Vic	Red clay loam	Cauliflower	Skywalker	Marco Montagna	24-Feb-10
4	Nairne, SA	Brown clay loam	Brussels sprouts	Millennium	Bill Frost	20-Jan-10
5	Manjimup, WA	Sandy loam	Cauliflower	Skywalker	Charlie Hewitt	10-Mar-10

4.3.2 Target Weeds

Trial Number	Location	Weeds
1	Gatton, Qld	Black pigweed (<i>Trianthema portulacastrum</i>), sowthistle (<i>Sonchus oleraceus</i>), dwarf amaranth (<i>Amaranthus macrocarpus</i>), barnyard grass (<i>Echinochloa crus-galli</i>)
2	Bathurst, NSW	Saffron thistle (<i>Carthamus lanatus</i>), chickweed (<i>Stellaria media</i>), pigweed (<i>Portulaca oleracea</i>), deadnettle (<i>Lamium amplexicaule</i>), Paterson's curse (<i>Echium plantagineum</i>), shepherd's purse (<i>Capsella bursa-pastoris</i>)
3	Werribee, Vic	Stinging nettle (<i>Urtica urens</i>), shepherd's purse (<i>Capsella bursa-pastoris</i>), wireweed (<i>Polygonum aviculare</i>), marshmallow (<i>Malva parviflora</i>), sowthistle (<i>Sonchus oleraceus</i>)
4	Nairne, SA	Fat hen (<i>Chenopodium album</i>), wireweed (<i>Polygonum aviculare</i>), capeweed (<i>Arctotheca calendula</i>)
5	Manjimup, WA	Wild radish (<i>Raphanus raphanistrum</i>), dock (<i>Rumex sp</i>), arrow leaf clover (<i>Trifolium vesiculosum</i>), fat hen (<i>Chenopodium album</i>), annual ryegrass (<i>Lolium rigidum</i>)

4.3.3 Treatments Applied

Treatment	Application Timing	Rate Product/ha	Irrigation
1. Untreated Control	Pre-plant		Management
2. Cultivation Pre-em herbicide# BARON WP	Pre-plant Pre-plant or immediately post-transplant 3 DAT	500-1000 g/ha	No irrigation*
3. Cultivation Pre-em herbicide# BARON WP	Pre-plant Pre-plant or immediately post-transplant 3 DAT	500-1000 g/ha	Irrigation
4. Cultivation Pre-em herbicide# GOAL	Pre-plant Pre-plant or immediately post-transplant 3 DAT	500-1000 g/ha	No irrigation*
5. Cultivation Pre-em herbicide# GOAL	Pre-plant Pre-plant or immediately post-transplant 3 DAT	500-1000 g/ha	Irrigation

*Broadcast irrigation not applied for at least 7 days following transplanting

DAT = days after transplanting

Note 1: The BARON WP use rate selected depended upon the soil type and weather conditions at the location. The low rate was used under cold wet conditions (winter) or on light to medium soils and the higher rate in warmer weather on heavier soils.

Note 2: Transplants were watered around the base of the plant for the first 7 days following transplanting.

**Pre-em Herbicide:* The following herbicides were used in these trials prior to transplanting, or immediately post-transplanting (0-2 DAT):

DUAL GOLD (S-metolachlor) – 1500 mL/ha applied immediately following transplanting in sites 2 and 4 and 2000 mL/ha in sites 1 and 5.

RIFLE 330 (pendimethalin) – 2500 mL/ha applied and incorporated by irrigation prior to transplanting in site 3.

4.3.4 Formulations

NUFARM RIFLE 330 HERBICIDE – an emulsifiable concentrate formulation containing 330 g/L pendimethalin as marketed by Nufarm Australia Limited.

DUAL GOLD HERBICIDE – an emulsifiable concentrate formulation containing 960 g/L S-metolachlor as marketed by Syngenta Crop Protection Pty Ltd.

BARON 400 WP SELECTIVE HERBICIDE – a wettable powder formulation containing 400 g/kg oxyfluorfen as marketed by Agnova Technologies Limited.

GOAL HERBICIDE – an emulsifiable concentrate formulation containing 240 g/L oxyfluorfen as marketed by Dow AgroSciences Limited.

4.3.5 Application Method

Trial Number	Location	Equipment	Nozzles	Pressure	Volume/ha
1	Gatton, Qld	Hand boom	11001 flat fan	290 kPa	209 L
2	Bathurst, NSW	Hand boom	11001 flat fan	250 kPa	210 L
3	Werribee, Vic	Hand boom	11001 flat fan	200 kPa	77 L
4	Nairne, SA	Hand boom	11001 flat fan	250 kPa	83 L
5	Manjimup, WA	Hand boom	11001 flat fan	250 kPa	400 L

4.3.6 Experimental Design

Trial Number	Location	Trial Design	Plot size
1	Gatton, Qld	Unreplicated demonstration	1 bed, 4 rows (1.5 m) X 7 m
2	Bathurst, NSW	Unreplicated demonstration	1 bed, 4 rows (1.5 m) X 7 m
3	Werribee, Vic	Unreplicated demonstration	1 bed, 4 rows (1.5 m) X 7 m
4	Nairne, SA	Unreplicated demonstration	1 bed, 2 rows (1.5 m) X 7 m
5	Manjimup, WA	Unreplicated demonstration	1 bed, 4 rows (1.5 m) X 7 m

5. RESULTS

The data presented are a selected summary designed to demonstrate the data trends seen from which the conclusions have been drawn.

These include a summary of weed control data for all weeds species in each trial at around 7-10 weeks following transplanting. In addition a summary of the crop safety data is given as well as the yield results for the two sites in which yield was recorded.

Statistical analyses were conducted using GenStat Release 11.1 (PC/Windows 2008 – Lawes Agricultural Trust, Rothamsted Experimental Station). The model included all treatment effects. Analysis of variance and least significant difference (LSD) procedures were used.

5.1 Project Component 1 – Herbicide Strategies

Results are summarised in Tables 1-10.

5.2.2 Residue Studies

Results are summarised in Tables 19-50.

Full analytical results are presented in the Agrisearch Analytical reports 10-0255O, 10-0255C, 10-0255G, 10-0255P and are presented in the report ‘Integrated Weed Management In Vegetable Brassicas, Australia, 2010 - A Study Conducted Under OECD Good Laboratory Practice [GLP]’ which has been provided to HAL as a separate document.

Table 19 Residues of Oxyfluorfen in Broccoli Treated with BARON WP via Field Trial 090615, Gatton Qld

Sample No.	Treatment Rate (g/ha)	Sampling Timing	Sampling Date	Oxyfluorfen (mg/kg)
090615-1	Untreated Control	--	15-Apr-10	<LOD
090615-3	500	First commercial harvest	15-Apr-10	<LOD

LOQ = Limit of Quantitation (as received basis) = 0.05 mg/kg for oxyfluorfen.

LOD = Limit of Detection (as received basis) = 0.02 mg/kg for oxyfluorfen

Note: Results for test samples are not corrected for recoveries.

Table 20 Residues of Oxyfluorfen in Broccoli Treated with BARON WP via Field Trial 090616, Mangrove Mountain, NSW

Sample No.	Treatment Rate (g/ha)	Sampling Timing	Sampling Date	Oxyfluorfen (mg/kg)
090616-1	Untreated Control	--	02-Aug-10	<LOD
090616-2	500+500	First commercial harvest	02-Aug-10	<LOD
090616-3	500	First commercial harvest	02-Aug-10	<LOD

LOQ = Limit of Quantitation (as received basis) = 0.05 mg/kg for oxyfluorfen.

LOD = Limit of Detection (as received basis) = 0.02 mg/kg for oxyfluorfen

Note: Results for test samples are not corrected for recoveries.

Table 21 Residues of Oxyfluorfen in Cauliflower Treated with BARON WP via Field Trial 090617, Bathurst, NSW

Sample No.	Treatment Rate (g/ha)	Sampling Timing	Sampling Date	Oxyfluorfen (mg/kg)
090617-1	Untreated Control	--	24-Aug-10	<LOD
090617-2	500+500	First commercial harvest	24-Aug-10	<LOD
090617-3	500	First commercial harvest	24-Aug-10	0.02*

LOQ = Limit of Quantitation (as received basis) = 0.05 mg/kg for oxyfluorfen.

LOD = Limit of Detection (as received basis) = 0.02 mg/kg for oxyfluorfen

Note: The results marked with the * are between LOD and LOQ. As the reported values are less than the LOQ, by definition, their accuracy and precision cannot be verified.

Note: Results for test samples are not corrected for recoveries.

Table 22 Residues of Oxyfluorfen in Cauliflower Treated with BARON WP via Field Trial 090618, Werribee, Vic

Sample No.	Treatment Rate (g/ha)	Sampling Timing	Sampling Date	Oxyfluorfen (mg/kg)

6. DISCUSSION

Trial data from eight sites across Australia confirmed the earlier findings that broadleaf rather than grass weeds represent the largest threat to vegetable brassica growers. In these studies over 22 different broadleaf weeds were present with *Stellaria media*, *Sonchus oleraceus*, *Chenopodium album* and *Malva parviflora* being the most ubiquitous.

Effective weed control in vegetable brassicas is best obtained when an integrated weed control program is followed. Whilst discussion of integrated systems is beyond the scope of this report, considerations of the need for an integrated system have been made in evaluating the results from the weed control strategies evaluated.

The application of BARON WP herbicide as a broadcast treatment has been shown to be a very effective tool which can be successfully used in broadleaf weed control when applied as a broadcast spray within 3 days following transplanting as per the label recommendations. The data, particularly from the Mangrove Mountain study clearly demonstrate the benefit of combining the application of BARON WP with a suitable pre-emergence herbicide such as DUAL GOLD. **This program should form the basis of an effective chemical weed control strategy for vegetable brassica growers.**

The pre-emergence herbicides, DUAL GOLD and RIFLE 330 were used in all studies. These treatments were effective and generally safe to the crop in most instances. This was not the case in the Gatton study however, where plant growth was significantly retarded by the application of DUAL GOLD. The inclusion of the BARON WP treatments caused no greater crop damage than was seen to be caused by the DUAL GOLD alone. Whilst the crop in this location was successfully harvested the actual harvest date was delayed by some considerable time. The application of DUAL GOLD can have a significant impact on crops grown in these high clay content soils and should be avoided. The application of pendimethalin (RIFLE 330) applied prior to transplanting would be a preferred option in these conditions.

Investigation of the benefits of applying BARON WP at 3-4 weeks following transplanting demonstrated no difference over and above applying BARON WP immediately following transplanting. Whilst data were not always statistically significant, a trend in the data suggested that leaving applications until this timing may result in poorer weed control as BARON WP essentially has pre-emergence weed control activity. Using BARON WP as a follow up treatment at low rates as either an over the top application or as an inter-row treatment was shown to have some merit, and in terms of crop safety, was similar to BARON WP applied at the early post-transplant timing. For example at Bathurst and Mangrove Mountain, in broccoli and cauliflower, the data suggested that control of the weed *Stellaria media* was improved by a split application of BARON WP following use of the pre-emergence herbicide DUAL GOLD. At Coldstream when applied to Brussels sprouts the split application caused a significant reduction in crop biomass compared to untreated plots whereas the single application applied at transplanting did not. Longer residual weed control may result from this application program, but to be effective, it was shown that the product would need to be applied to weed free soil. The use of BARON WP alone to achieve later post-emergence weed control cannot be supported.

The herbicide FRONTIER-P (dimethenamid-P) was also evaluated as an alternative to the currently used pre-emergence herbicides. Whilst effective weed control was achieved, data indicated that performance was generally less than that provided by the current standards where applied alone or in a program with BARON WP. In addition, some crop safety issues were identified with FRONTIER-P generally showing a lower level of selectivity than the current standards and as such cannot be recommended for further development.

The use of hand weeding or simulated mechanical weeding was shown to provide a variable level of weed control across the trial locations. This was mainly due to the timing of the weed control, the weeds present and the location of the weeds in the planting architecture. The effectiveness of all of the currently registered pre-emergence herbicides can be reduced when inter-row cultivation is practised. The majority of these herbicides form a protective barrier on the soil surface which can be broken by cultivation and allow weeds to successfully germinate. However inter-row cultivation cannot be discounted from vegetable brassica agronomy, for as well as providing an alternative form of weed control, soil aeration is essential in some areas for best crop growth to be achieved. This was particularly apparent in the Bathurst study. The field trial area was not cultivated for the reasons stated whilst the remainder of the crop was. Plants in the test area failed to reach the same potential as the bulk of the crop and head size was significantly smaller.

The need to control broadleaf weeds which ‘escape’ early weed control strategies was further addressed through the use of the non-selective knockdown herbicides glufosinate-ammonium (BASTA), carfentrazone-ethyl (SPOTLIGHT PLUS) and paraquat (GRAMOXONE 250) as well as BARON WP through shrouded sprayers. BARON WP applied through a shrouded sprayer as an alternative to applying the treatment ‘over the top’ would be effective. Application rates of 150-500 g/ha were safe but generally were no better than when BARON WP was applied at transplanting.

The use of BASTA (glufosinate-ammonium) and SPOTLIGHT PLUS (carfentrazone-ethyl) applied via this technique all gave effective weed control and will offer an alternative to residual herbicides or cultivation. However, the major concern is with spray drift escaping from the unit and causing damage to the off-target crop. A purpose built unit was used in all trials to simulate commercial application and is shown in Figure 1.

A level of crop phytotoxicity was seen in all trials but varied between locations. Further, a high level of variability was seen within treatments in some trials and was a reflection of the low tolerance to drift when spraying on uneven surfaces with such an application method. General damage was greatest at 7 days following application and was evident as spotting on the outer leaves. SPOTLIGHT PLUS and GRAMOXONE generally caused a significantly higher level of damage than BASTA, which was particularly evident at Mangrove Mountain where significant spray escape occurred. Phytotoxic symptoms disappeared over time and generally did not have a long term impact upon harvestable produce. However vegetable brassica growers have a low tolerance to herbicide effects as the appearance of the produce is a critical determinant of marketability. For this reason the application of these treatments, particularly SPOTLIGHT PLUS and GRAMOXONE are considered very high risk.

When tank-mixed with BARON WP however phytotoxic symptoms were often greater than with each of the knockdown herbicides applied alone and longer term reductions in crop vigour also were evident and generally significantly greater than when each of the products were applied alone. A tank mix of BARON WP plus either BASTA, SPOTLIGHT PLUS or GRAMOXONE 250 cannot be recommended for further evaluation due to the high risk of a significant level of crop damage occurring.

GRAMOXONE 250 currently has a registration for use via shielded equipment in vegetables and could be used as a salvage treatment where equipment is available.

The development of an effective shrouded sprayer for use in vegetable brassicas is essential for this method of weed control to be adopted.

The importance of incorporating oxyfluorfen within 7 days of application was also investigated with the inclusion of demonstration sites at five locations. Both BARON WP and GOAL were applied at 2-3 days following transplanting and one section irrigated and one left with hand watering around the base of the plants. Differences in weed control were seen in three of the sites and were shown to growers at each of the field days to demonstrate the effect.

Figure 1 Shrouded Spray Unit

7. TECHNOLOGY TRANSFER

7.1 Field Days

Field days were conducted at each of the eight sites across Australia. Two separate days were generally conducted at each site one targeting industry representatives and one targeting growers. Field days were attended by a range of agronomists and field staff representing resellers, processors and chemical manufacturers as well as other researchers.

Data generated from this project will be used in product registrations for some actives and as such will not occur for some time following the projects completion. Companies whose products have been included in the study have been regularly consulted throughout the course of the project and will be involved in technology transfer following product registration which result from this work.

7.2 Grower Resource Pack

The grower resource pack which has been generated as part of this project will provide the basis for integrated weed control measures in these crops. The grower resource pack is presented as a comprehensive brochure covering all aspects of brassica production including crop planning, crop production and post-harvest activities to ensure best possible outcomes for weed control are achieved. Any future measures which may be adopted from this project will need to be incorporated into the document at a later date.

In addition, a poster highlighting the importance of sprayer hygiene and how best to achieve this has been produced.

Both articles have been provided to HAL as attachments to this report and are publicly available through the Ausveg website at <http://ausveg.com.au/intranet/technical-insights/overview.htm> or by contacting the author at les.mitchell@agrisearch.com.au.

A range of other written material was produced including milestone reports and articles for magazines.

Date	Grower Field Day

	Industry meetings
October/November 2009	Meetings with AgAware consulting, Agnova Technologies, Bayer CropScience and FMC Australia discussing project design
March 2010	Meetings with Agnova Technologies and FMC Australia discussing progress and development options
March 2011	Meetings with Agnova Technologies and Bayer crop science re registration options
March 2011	Meeting with Syngenta regarding current registration status

Attendance at the field days varied from 2-25 growers and industry and 1-2 at industry field days.

Figure 2 Field Day Werribee

8. RECOMMENDATIONS

The major outcome of this project is that speculation over the use of BARON WP as a later post-emergence product in vegetable brassicas has been clarified. The study results demonstrate that when used according to label recommendations in conjunction with a registered transplant herbicide excellent weed control can be achieved. Later application uses will offer no significant benefit to the current registered practices and may lead to herbicide soil residue issues which are also addressed on the product label.

Sufficient data have been generated to support the registration application of BASTA for use as a salvage product using shrouded spray equipment and has shown that GRAMOXONE 250, which is registered for this application, can also be used. However any such commercial usage is contingent upon the development of an effective shrouded sprayer being available.

These two applications however are only part of an integrated approach which is required to achieve sustainable weed control in vegetable brassica production and a grower resource pack has been developed to provide essential information into achieving this result.

Comments from field days indicated surprise at the level of crop safety seen in all studies. In the absence of other explanations; sprayer hygiene and accurate calibration have been identified as an issue to ensure better pesticide efficiency with improved crop safety.

A program to improve understanding of the need for first class hygiene when using the same spray unit for applying different pesticide types is recommended.

9. ACKNOWLEDGMENTS

Agrisearch staff who contributed to this project included: Richard Holzknecht, Joel Gorman, Greg Murdoch, Peter Melville, Neil Adams, Marco Montagna, Samantha Strano, Bill Frost, Veronica Smith and Charlie Hewitt.

Agrisearch analytical staff members assistance, led by Ross Shields and Lan Byrnes is gratefully acknowledged.

The assistance of Philip Frost from Peracto who completed the trial in Tasmania is gratefully acknowledged.

The assistance of staff from EE Muir and Sons, Elders Gatton and Ace Ohlssenen organising field days was invaluable.

Growers who provided sites included: Max Durham, Paul Gretch, Michael Cook, Bruce Adams, Stan Velisha and John Cranwell.

Controlling Weeds in Broccoli, Cauliflower and Brussels Sprouts

A Guide to Effective Weed Control in Australian Brassicas

Background

Effective weed management is an essential requirement for reliably achieving high quality brassica produce. By taking a long term view of weed management and adopting an integrated weed management system, you can consistently control the weeds that compete with brassica crops.

In-crop weed management requires a long term integrated approach.

Weed management commences prior to planting of the crop and does not stop until the crop has been harvested and residual produce/weeds are destroyed or cultivated.

This long term approach requires attention to both current and future brassica crops. There are several methods and herbicide options available.

Conducting all activities at the right time is the key to successful integrated weed control. Being too late reduces effectiveness and can lead to poor weed control.

Key Points

- Reduce the seed bank prior to planting
- Transplant into weed free beds
- Apply appropriate pre-emergence herbicides before and/or immediately post transplanting
- Herbicides MUST be used correctly
- Inter-row cultivate OR use knockdown herbicide through protected sprayers to control weeds later in the crop as required
- Post-harvest clean up is essential

Introduction

This brochure is a guide to integrated weed management in Australian broccoli, cauliflower and Brussels sprout crops. It provides an overview of weed management methods in these crops based on research conducted for Horticulture Australia Limited. There are 3 key steps to effective weed management. These are:

1. Planning your rotations
2. Identify your weeds
3. Develop your weed management strategy

If the person doing the work can reasonably answer these questions, then they will have greater directness about their work, its importance and impact for them. The person will feel more confident in contributing more of themselves to the doing of the work.

"The Vegetable Industry Development Program is funded by HAL using the vegetable levy and matched funds from the Australian Government".

Vegetable Industry Development Program

Step 2: Identify Your Weeds

The key to getting the most from an integrated weed management system is to understand the weeds which will be a problem in your crop.

To most growers this will come from experience in individual blocks and from observation of the major weeds present in your district.

There are two main groups of weeds that cause problems in vegetable brassicas in Australia;

- broadleaf weeds, and
- grass weeds.

It is important to identify which weeds are present in your crops as herbicides and control methods will vary accordingly. With this knowledge a weed control plan can be developed which should give ‘best possible’ outcomes for that weed or weed spectrum.

11 key broadleaf weeds have been identified that cause problems to brassicas in Australia. Grass weeds are seldom a problem in brassica crops as they are controlled by the management strategies used for broadleaf weeds. A range of products are registered for their control.

Key Points

- Identifying present weeds will determine which herbicide you can use
- Grass weeds do not need to be considered but can be a problem if knockdown herbicides are not used

Key Points

- Use rotation crops to control weed seed banks between brassica crops
- Using herbicides at the right time is crucial

"The Vegetable Industry Development Program is funded by HAL using the vegetable levy and matched funds from the Australian Government".

Vegetable Industry Development Program

Step 3: Develop Your Weed Management Strategy

There are five possible stages in which weed control will be most effective. These are pre-planting, transplanting, early in-crop and late in-crop, post-harvest and when the paddock is fallow. There are several options per stage depending on your strategy and the density and diversity of the weed population.

Pre-Planting

In-crop weed management is easier and more effective where longer rotations and suitable break crops to reduce weed seed bank are used.

However in intensive production systems where crop rotations times are tight this option can be difficult. Getting crop rotation correct and minimising weed populations in the previous crop will reduce weed pressure in the current crop.

Successful weed control commences with transplanting into a weed free seed bed. Best results are obtained using a combination of cultural and chemical controls. There are two main options:

Option 1

Form beds well before planting, irrigate to germinate an initial flush of weeds. These weeds can be controlled by spraying with a knockdown herbicide. Alternatively, weeds can be controlled with a very shallow cultivation.

Option 2

Form beds just before planting, with a final cultivation to prepare the seedbed and control any emerged weeds. This is discouraged in paddocks with substantial weed burdens, but does minimise pre-plant herbicide applications.

Herbicide options in the pre-plant management phase are all knockdown herbicides with no residual activity. The options at this time are glyphosate, paraquat or diquat. The choice of the correct herbicide will depend upon the weeds present, their size and the herbicide cost. It is best to apply these products when weeds are small as lower rates can be used and better coverage obtained leading to more effective control at lower cost.

Key Points

- Forming beds well before planting then using a knockdown herbicide and cultivating any emerged weeds is the preferred method
- In beds with low weed populations cultivation can be carried out at time of bed formation to reduce herbicide applications

Broadleaf Weeds

- Wild Radish, *Raphanus raphanistrum*
- Redroot Amaranth / Prince-of-Wales Feather, *Amaranthus spp.*
- Hogweed / Wireweed, *Polygonum aviculare*
- Black Berry Nightshade, *Solanum nigrum*
- Pigweed, *Portulaca oleracea*
- Sowthistle / Milk Thistle, *Sonchus spp.*
- Fat Hen, *Chenopodium album*
- Wild Turnip, *Brassica spp.*
- Annual Nettle / Stinging Nettle, *Urtica urens*
- Chickweed, *Stellaria media* (*suppression*)
- Shepherd's purse, *Capsella bursa-pastoris*

Grass Weeds

- Annual ryegrass, *Lolium rigidum*
- Winter grass, *Poa annua*
- Barnyard grass, *Echinochloa spp.*
- Summer grass, *Digitaria spp.*

Vegetable Industry Development Program

Actions Around Planting (Transplanting)

Transplanting is the most critical time for obtaining good in-crop weed control. This is when most herbicides available for use in vegetable brassicas are applied. There are currently

six different actives which are registered for application just before or just after transplanting, and before weeds have emerged.

Herbicide	Trade Name	Application Timing	Key Weeds Controlled	Critical Comments
Chlorthal-dimethyl	Dacthal 900 WG	Immediately post transplant	Grasses, nettles, milk thistle, amaranth, pigweed, chickweed, wireweed	Does not control brassica weeds or marshmallow. Requires incorporation by irrigation immediately after transplanting. 8 month plant back for sensitive crops (i.e. lettuce).
Metolochlor S-metolochlor	Dual/Dual Gold Plus and other	Immediately post transplant	Grasses, nettles, milk thistle, nightshade, amaranth, pigweed, chickweed, wireweed	Does not control brassica weeds or marshmallow. Requires incorporation by irrigation within 24 hours after transplanting. Can reduce crop growth in soils with low organic matter or > 60% silt or fine sand.
Oxyfluorfen EC	Goal and others	Pre-plant	Grasses, brassica weeds, nettles, milk thistle, pigweed, chickweed, wireweed	Requires incorporation by irrigation within 7 days of application. Transplanting can break herbicide barrier. 6 month plant back for sensitive crops (i.e. onions).
Oxyfluorfen WP	Baron 400 WP	Immediately post transplant (within 3 days)	Grasses, brassica weeds, nettles, milk thistle, pigweed, chickweed (Suppression), wireweed	Requires incorporation by irrigation within 7 days of application. Can cause crop damage on sandy soils and when applied in cold weather.
Pendimethalin	Stomp and others	Pre-plant	Grasses, fat hen, milk thistle, pigweed, chickweed, wireweed	Requires incorporation by irrigation within 5 days of application. Transplanting can break herbicide barrier. Can cause crop damage when applied in cold weather. 12 month plant back for sensitive crops (i.e. silver beet).
Propachlor	Ramrod	Immediately post transplant	Grasses, nettles, fat hen, milk thistle, amaranth, chickweed, wireweed	Does not control brassica weeds or marshmallow Requires incorporation by irrigation within 24 hours after transplanting.
Trifluralin	Triflur and others	Pre-plant	Grasses, amaranth, pigweed, wireweed	Requires incorporation by irrigation within 6 hours of application. Transplanting can break herbicide barrier.

To effectively control the widest weed spectrum for an extended period a split application of metolochlor OR pendimethalin followed by Baron 400 WP provides the best result. However growers need to evaluate their individual situations with emphasis on environment, weeds present, time of the year, crop rotation, irrigation methods and herbicide cost before making a final decision.

Early In-Crop

Options for good control are limited if weeds develop in-crop. Grass weeds can be easily controlled using a number of group A herbicides which are registered in these crops.

These include fluazifop-p-butyl (Fusilade), sethoxydim (Sertin), quizalofop and clethodim (Select). Note these products may not be registered in all crops (check labels for registration rates and withholding periods).

Broadleaf weeds can only be killed by cultivation or by inter-row spraying with a shielded spray unit. There is an optimal time when cultural operations are most effective. If done too early the full benefits of the pre-emergence herbicide will be lost as there is time for further weeds to germinate before the canopy closes over. If done too late crops may just be transplanted and some damage can occur.

The actual timing depends upon the crop, the weeds and the time of the year, however this is generally around 4 weeks following transplanting. In many areas cultivation is also a necessary part of the production process and is needed to ensure good soil aeration and to optimise crop growth.

An alternative option is to control weeds through the use of directed inter-row spraying with non selective herbicides using shielded spraying equipment. This method is effective and very efficient, however it does come with some risk, as any herbicide escape can lead to severe injury or death to the crop. The shielded unit must be well made and maintained to ensure that herbicide does not escape when spraying on uneven surfaces. Currently the only product registered for this use is Gramoxone. Please consult the product label and consult your local agronomist prior to adopting this form of in-crop weed control.

Key Points

- Grass weeds can be killed using group A herbicides, but options are limited for broadleaf weeds
- Cultivation and inter-row shielded spraying are the only options to control broadleaf weeds prior to canopy

"The Vegetable Industry Development Program is funded by HAL using the vegetable levy and matched funds from the Australian Government".

Late In-Crop and Post-Harvest Weed Control

Once a crop is established and canopy closure achieved it will suppress the growth of most weed species. However species such as Fat Hen, Radish and Potato Weed can grow rapidly and rise above the crop during the last few weeks and interfere with harvest. These weeds can also set seeds and reduce the effectiveness of your integrated weed control management. It is important to reduce their numbers and subsequent seed set.

Hand weeding is the only way to reduce weed numbers prior to harvest and whilst this may be expensive in the short term, the longer term benefits of reducing the weed seed bank, will be seen in future crops. Following harvest, effective weed clean up and maintenance of a clean fallow between crops is essential.

The use of cultivation or non selective herbicide sprays, or a combination of both will ensure clean fields and easier and more cost effective weed management in future crops.

Key Points

- It is important to control weeds prior to harvest to reduce the opportunity for weeds to set viable seed.
- Hand weeding is an expensive option but will reduce the subsequent seed banks and costs in the long term.

Why Cleaning Spray Tanks Is Important?

- Crop protection products and associated adjuvants can leave sticky oily residues on all internal surfaces of spray equipment.
- Small amounts of herbicide residue if not properly removed can cause serious damage to sensitive crops.
- Small amounts of fungicide or insecticide residue can activate some herbicides causing greater levels of crop damage than would be expected.
- Small amounts of residue from some actives could lead to MRL's being exceeded.
- Pesticide residues can cause corrosion of sprayer parts and rubber seals reducing the effective life of the sprayer and increasing the likelihood of blowouts.

What to Clean With

- All pesticide labels list the appropriate agent to use to effectively remove residues of that active from internal sprayer parts.
- **READ THE LABEL** and use the correct boom cleaner.

How to Clean

- Always wear protective clothing when cleaning spray equipment, as recommended on the product label.
- Fill the tank with clean water and the recommended tank cleaner.
- Operate the pump and flush the cleaning solution through all hoses, strainers, screens, nozzles and the boom.
- Remove nozzles, screens and strainers and clean them separately in a bucket containing the recommended cleaner.
- Rinse the system with clean water.

Disposal

- Dispose of rinseate onto bare soil or into collection pits away from streams and water ways.
